We study a space-time finite element approach for the nonhomogeneous wave equation using a continuous time Galerkin method. We present fully implicit examples in $1+1$, $2+1$, and $3+1$ dimensions using linear quadrilateral, hexahedral, and tesseractic elements. Krylov solvers with additive Schwarz preconditioning are used for solving the linear system. We introduce a time decomposition strategy in preconditioning which significantly improves performance when compared with unpreconditioned cases.

arXiv:gr-qc/0601099v1 24 Jan 2006

I. INTRODUCTION

Space-time finite elements provide some natural advantages for numerical relativity. With space-time elements, time-varying computational domains are straightforward, higher-order approaches are easily formulated, and both time and spatial domains can be discretized using a single unstructured mesh. However, while continuous Galerkin approaches employing space-time finite elements have found use in many engineering applications [1], [2], [3], [4], [5], they have not been used in numerical relativity. Recent numerical relativity evolutions using finite elements employ discretization of the space domain and marching in time rather than simultaneous discretization of both space and time domains [6], [7], [8].

We investigate a space-time finite element method similar to [9] using continuous approximation functions in both space and time to explore its use for numerical relativity simulations. The main purpose of this paper is to present our numerical results. We present a time-parallel preconditioning strategy for use with continuous space-time elements and Krylov solvers, and explore numerical results in $1+1$ dimensions and higher.

Many space-time approaches to the wave equation exist (see [10], [11], [12], [13]). Our approach is different in that we do not use time slab finite elements, which are continuous in a limited domain of time (the time slab) but discontinuous between neighboring time slabs. Instead, we discretize space and time together for the entire domain using a finite element space which does not discriminate between space and time basis functions and consider iterative solution methods with a time decomposition preconditioner. This approach has advantages for more general finite element spaces and parallelization. In this paper, however, we restrict ourselves to structured space-time finite elements and present the results obtained on a single processor in order to better compare results and performance with other approaches to solving the wave equation.

We consider the following nonhomogeneous wave equation problem with the initial and boundary value problem to find $u(\mathbf{x},t)$ such that

$$\begin{aligned} \frac{\partial^2 u}{\partial t^2} - \triangle u = f \quad &\text{in} \quad \Omega \times [0,T], \\ u = u^0 \quad &\text{on} \quad \Omega \times \{t=0\}, \\ u_t = v^0 \quad &\text{on} \quad \Omega \times \{t=0\}, \\ u_n = 0 \quad &\text{on} \quad \partial\Omega \times [0,T], \end{aligned} \tag{1}$$

where Ω is a bounded domain in R^d, $d=1,2,3$ and u_n is the outward pointing normal derivative. As in [9], Eq. (1) is re-written to be first order in time by introducing an auxiliary variable, $v = u_t$:

$$\begin{aligned} \frac{\partial v}{\partial t} - \triangle u = f \quad &\text{in} \quad \Omega \times [0,T], \\ -\frac{\partial u}{\partial t} + v = 0 \quad &\text{in} \quad \Omega \times [0,T], \\ u = u^0 \quad &\text{on} \quad \Omega \times \{t=0\}, \\ v = v^0 \quad &\text{on} \quad \Omega \times \{t=0\}, \\ u_n = 0 \quad &\text{on} \quad \partial\Omega \times [0,T], \\ v_n = 0 \quad &\text{on} \quad \partial\Omega \times [0,T]. \end{aligned} \tag{2}$$

We use a nonhomogeneous Dirichlet boundary condition on the initial boundary $\Omega \times \{t = 0\}$, and a homogeneous Neumann boundary condition for $\partial\Omega \times (0, T]$. No boundary condition is set at $\Omega \times \{t = T\}$ to avoid overspecifying the problem. Consequently, the evolution equations themselves become an effective boundary condition by determining the values for the solution at $\Omega \times \{t = T\}$.

The space $L^2(\Omega)$ is defined as the closure of $C^\infty(\Omega)$ in the norm,

$$||u||_{L^2(\Omega)} = \left(\int_\Omega |u|^2 dx \right)^{1/2} < \infty.$$

The H^1-seminorm and norm of $u \in H^1(\Omega)$ are, respectively,

$$|u|^2_{H^1(\Omega)} = \int_\Omega |\nabla u|^2 \, dx; \quad ||u||^2_{H^1(\Omega)} = |u|^2_{H^1(\Omega)} + ||u||^2_{L^2(\Omega)}.$$

We define the Hilbert space $L^2([0, T], H^1(\Omega))$ by

$$||w||_{L^2([0,T],H^1(\Omega))} = \Big(\int_O^T ||w(\cdot, t)||^2_{H^1(\Omega)} \, dt \Big)^{1/2}.$$

For the space-time finite element space of $n = 1, 2, 3$ spatial dimensions, we consider the standard finite element space of $n + 1$ dimensions. Therefore our finite element space V is the space of piecewise polynomial functions $\phi : \Omega \times (0, T] \to R$.

The weak form is to find approximate solutions $\tilde{u}, \tilde{v} \in L^2([0, T], H^1(\Omega))$ such that

$$M(\tilde{u}, \tilde{v}, \phi) = 0 \tag{3}$$
$$N(\tilde{u}, \tilde{v}, \phi) = 0 \quad \forall \phi \in L^2([0, T], H^1(\Omega)), \tag{4}$$

where

$$M(\tilde{u}, \tilde{v}, \phi) = \int_{\Omega \times [0,T]} \left(\frac{\partial \tilde{v}}{\partial t} \phi + \nabla \tilde{u} \cdot \nabla \phi - f\phi \right) ds, \tag{5}$$

$$N(\tilde{u}, \tilde{v}, \phi) = \int_{\Omega \times [0,T]} \left(-\frac{\partial \tilde{u}}{\partial t} \phi + \tilde{v}\phi \right) ds. \tag{6}$$

Motivated by the success of domain decomposition methods for general sparse matrices [14], [15], [16], we also examine additive Schwarz methods [17], [18], [19], [20], [21] with a time decomposition preconditioning strategy. While additive Schwarz preconditioning has been applied to hyperbolic problems before [22], [23], applying additive Schwarz preconditioning to space-time elements using a time decomposition strategy is unique to this work.

II. NUMERICAL RESULTS

In this section we present solutions to the nonhomogeneous wave equation using space-time elements in various dimensions. We use uniform structured meshes to better compare results with other approaches to solving the wave equation. Solutions presented are produced by a single linear solve of the system in Eqs. (3)–(4). All codes presented use PETSc [24], [25], [26]; the linear solve residuals given (labeled "Final Residuals") are the absolute residual norms,

$$r = ||Ax - b||_{L_2} \tag{7}$$

for the linear system $Ax = b$ where A is the system matrix, x is the solution, and b is the system right hand side vector for both $\tilde{u}$ and $\tilde{v}$. We use the L_∞ norm for reporting differences between the analytic and approximate solution:

$$||e||_{L_\infty} = \max |e^i|, \tag{8}$$

for vector e. For Krylov solve examples, the initial guess given for the solution is always zero.

n_x	n_t	$\| (\tilde{u} - U_e) \|_{L_\infty}$	rate
60	60	2.21×10^{-2}	–
120	120	5.11×10^{-3}	2.08
240	240	1.26×10^{-3}	2.01

TABLE I: Convergence using LU decomposition of a space-time element simulation with solution given by Eq. (9). There are $(n_x - 1)(n_t - 1)$ total elements in the mesh. The number of nodes in the x and t directions are n_x and n_t, respectively. Using linear elements, we expect second order convergence in the L_∞ norm. The convergence rates reported are given by rate $= \ln(E_2/E_1) / \ln(h_2/h_1)$ where h_1, h_2, E_1, E_2 are the successive quadrilateral lengths and L_∞ norms, respectively.

Solver Type	Preconditioner	iterations	Final Residual	$\| (\tilde{u} - U_e) \|_{L_\infty}$
GMRES	none	5127	10^{-5}	2.20×10^{-2}
GMRES	none	2000	10^{-2}	3.68×10^{-1}
LSQR	–	5000	10^{-3}	2.48×10^{-1}
GMRES	Jacobi	6000	10^{-2}	8.68
GMRES	Block-Jacobi	1	10^{15}	–

TABLE II: Various linear solver tests to solve the $1+1$ problem on a 60^2 structured mesh. GMRES performed the best, but required a very large number of iterations. LSQR is similar to a direct method and cannot be preconditioned in PETSc. Jacobi and Block-Jacobi preconditioning made GMRES convergence even worse than unpreconditioned.

A. $1+1$ Dimensions

For $1+1$ dimensions, we consider the nonhomogeneous wave equation with solution

$$U_e(x,t) = \exp\left[-(x - \cos t)^2\right] \tag{9}$$

on a domain of $x = [-5, 5]$ and $t = [0, 10]$. We choose the appropriate source term, f, in Eq. 1

$$f \;=\; -2\,(\cos t)\, e^{-(x-\cos t)^2} \left(2\cos^3 t - 4\,x\cos^2 t + 2\,x^2\cos t - 2\,\cos\, t + x\right), \tag{10}$$

and initial conditions to produce this test problem solution. Solving this system via LU decomposition with linear rectangular elements we observe the expected second order convergence, shown in Table I. Since scaling with problem size using LU decomposition for a banded matrix is $O\left(Nb^2\right)$ – where N is the size of the matrix and b is the bandwidth – LU is entirely inadequate for large problems with space-time elements. Krylov solvers [27], like GMRES [28], are much more suitable for such problems.

We tested a variety of solvers and preconditioners available in PETSc [24], [25], [26] for the problem using a 60^2 structured mesh. The results are summarized in Table II. While GMRES converges without preconditioning, it requires a high number of iterations to obtain a physically meaningful result. Preconditioning with Jacobi or Block-Jacobi does not improve the convergence rate. However, neither Jacobi nor Block-Jacobi preconditioning offer much flexibility with respect to the geometry of the problem. Additive Schwarz offers more flexibility in preconditioning this hyperbolic problem.

We follow a time decomposition strategy for additive Schwarz, as illustrated in Figure 1. The domain of the problem is split into separate subdomains of time slabs. Each subdomain overlaps the face cells of its neighbors. The much smaller linear system of each subdomain is subsequently solved, either by GMRES or by LU decomposition, and the result used for preconditioning the global system. We respect the original boundary conditions for the subspace interface condition: Dirichlet for $t = (t_{n-1} - \text{overlap})$ and evolution equation determined for $t = (t_n + \text{overlap})$ where t_n is the n-th time decomposition.

Results for time decomposition of a 60^2 mesh are summarized in Table III. Figure 2 shows plots of the solution after 1, 10, 100, and 500 GMRES iterations for the twelve subdomain additive Schwarz case. Subdomains were defined for this case by equally dividing up the global domain into time slabs consisting of 5 or 6 nodes each in the time direction.

The additive Schwarz preconditioner gives excellent performance compared to GMRES alone and provides a scalable alternative to LU decomposition for large problems. Furthermore, the additive Schwarz preconditioner is already suitable for time-parallel computation; each processor would take a portion of the time subdomain in preconditioning. Spatial domain decomposition could also be explored in connection with time decomposition; however, we restrict our attention to time decomposition here.

Solver Type	Preconditioner	# of subdomains	iterations	Final Residual	$\| (\tilde{u} - U_e) \|_{L_\infty}$
GMRES	ASM	4	100	10^{-4}	2.15×10^{-2}
GMRES	ASM	4	500	10^{-5}	2.21×10^{-2}
GMRES	ASM	5	200	10^{-4}	2.22×10^{-2}
GMRES	ASM	6	200	10^{-4}	2.50×10^{-2}
GMRES	ASM	10	500	10^{-4}	2.27×10^{-2}
GMRES	ASM	12	500	10^{-4}	2.39×10^{-2}

TABLE III: GMRES results using additive Schwarz method (ASM) preconditioning with a time decomposition strategy for the $1+1$ dimension case using a 60^2 structured mesh. The column labeled "Final Residual" gives the absolute residual norm for the linear solve. All the results show significant improvement over the comparable unpreconditioned GMRES case shown in Table II. Increasing the number of time subdomains generally requires more GMRES iterations to achieve comparable error residuals; however, the preconditioner is potentially faster with more subdomains. Also, the preconditioner would be more scalable in parallel when using more subdomains.

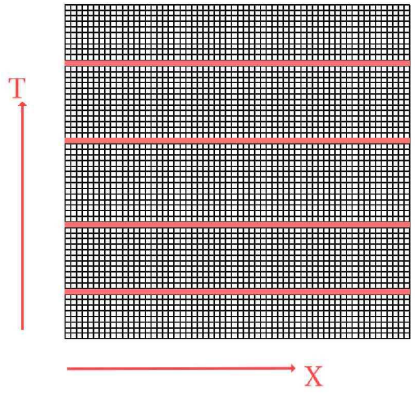

FIG. 1: The 60^2 mesh used for the $1+1$ dimension simulations. Here the entire mesh is divided into five subdomains in time for use in preconditioning. The linear systems resulting from each subdomain are solved and the result used for preconditioning the global linear system. The subspace interface condition is the same as for the original boundary conditions: Dirichlet for $t = (t_{n-1} - \text{overlap})$ and evolution equation determined for $t = (t_n + \text{overlap})$ where t_n is the n-th time decomposition. This preconditioner is also time-parallel: each time subdomain could be solved simultaneously on a different processor. Spatial domain decomposition could also be applied, but we only examine time decomposition here.

B. $2+1$ Dimensions

For $2+1$ dimensions, we modify the solution to be

$$U_e(x, y, t) = \exp\left[-(x - \cos t)^2 - (y + \sin t)^2\right]. \tag{11}$$

on a domain of $x, y = [-4, 4]$ and $t = [0, 4]$. The linear system is constructed using linear hexahedral elements giving second order convergence for the system.

A time decomposition strategy for preconditioning is also explored in $2+1$. Like the $1+1$ case, employing a time decomposition strategy with additive Schwarz preconditioning significantly improves performance when compared to using GMRES alone or LU decomposition. Table IV gives a summary of results obtained using a $40 \times 40 \times 20$ mesh. Performance times given are the solve times obtained on AMD opteron 250 processor with a clock speed of 2.4 GHz using the PETSc timing utility.

GMRES without preconditioning is ineffective for this problem due to the slow convergence rate. As expected, LU decomposition is also ineffective due to poor scaling as the problem size grows. In contrast, GMRES with additive Schwarz method (ASM) preconditioning using a time decomposition strategy is significantly more effective. Figure 3 shows plots of the solution after 10, 50, 100, and 500 GMRES iterations for the five subdomain ASM preconditioned case. As in the $1+1$ cases, the ASM preconditioner is time-parallel: parallelization can be achieved by simultaneously solving each time subdomain on a different processor.

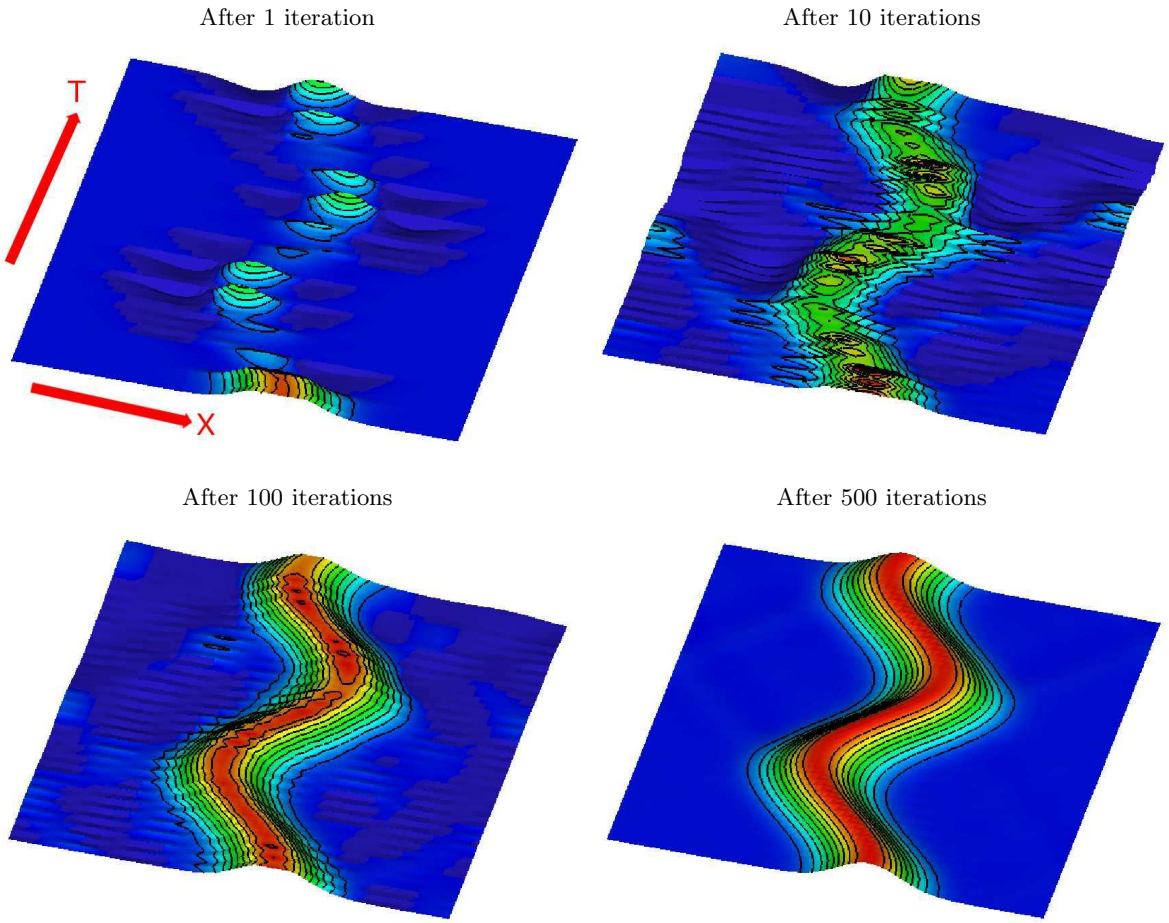

FIG. 2: An additive Schwarz preconditioned example using twelve subdomains in time on a 60^2 structured mesh, referenced in Table III. The plots show the solution after 1,10,100, and 500 GMRES iterations. Unlike time marching methods, the solution is constructed at all times simultaneously. The preconditioner substantially speeds up this process; evidence of the twelve additive Schwarz time subdomains is apparent after the first iteration of GMRES.

C. $3+1$ Dimensions

For $3+1$ dimensions, we select the solution to be

$$U_e\left(x,y,z,t\right)=\exp\left[-\left(x-\frac{1}{2}\cos t\right)^2-\left(y+\frac{1}{2}\sin t\right)^2-\left(z+\frac{1}{2}\cos t\right)^2\right]. \tag{12}$$

on a domain of $x,y,z=[-2.5,2.5]$ and $t=[0,5]$. The linear system is constructed using linear tesseractic elements consisting of 16 nodes per element, giving second order convergence for the system. Tesseracts are the higher dimensional analogue of hexahedra [29]. Table V gives a summary of results obtained using a 18^4 mesh.

Figures 4–5 show plots of the solution at selected time slices; Figure 5 shows the nine subdomain additive Schwarz preconditioned case at 10, 50, 100, and 750 GMRES iterations.

III. CONCLUSIONS

We have numerically examined space-time finite elements for the nonhomogeneous wave equation, testing several types of linear solvers and preconditioners in several dimensions. The motivation of this study is to explore the performance issues surrounding the use of space-time elements in the context of numerical relativity. Fully unstructured

Solver Type	Preconditioner	# of subdomains	iterations	Final Residual	$\| (\tilde{u} - U_e) \|_{L_\infty}$	Time (sec)
LU	-	-	-	10^{-14}	2.73×10^{-2}	2.1×10^3
GMRES	none	1	3000	10^{-2}	2.10×10^{-1}	2.8×10^3
GMRES	ASM	4	500	10^{-4}	2.92×10^{-2}	1.5×10^2
GMRES	ASM	4	1000	10^{-5}	2.77×10^{-2}	4.0×10^2
GMRES	ASM	5	500	10^{-4}	2.90×10^{-2}	1.5×10^2
GMRES	ASM	5	1000	10^{-4}	2.77×10^{-2}	4.1×10^2

TABLE IV: Linear solve results for the $2+1$ dimension case using a $40 \times 40 \times 20$ structured mesh. The column labeled "Final Residual" gives the absolute residual norm for the linear solve. The additive Schwarz preconditioned cases show significant performance gain over the comparable unpreconditioned GMRES case and LU case. The performance times, given in seconds, were obtained using the PETSc timing utility running on an AMD opteron 250 processor. The GMRES simulations required significantly less memory than LU decomposition. Figure 3 shows the solution for the five subdomain ASM case after 10, 50, 100, and 500 GMRES iterations.

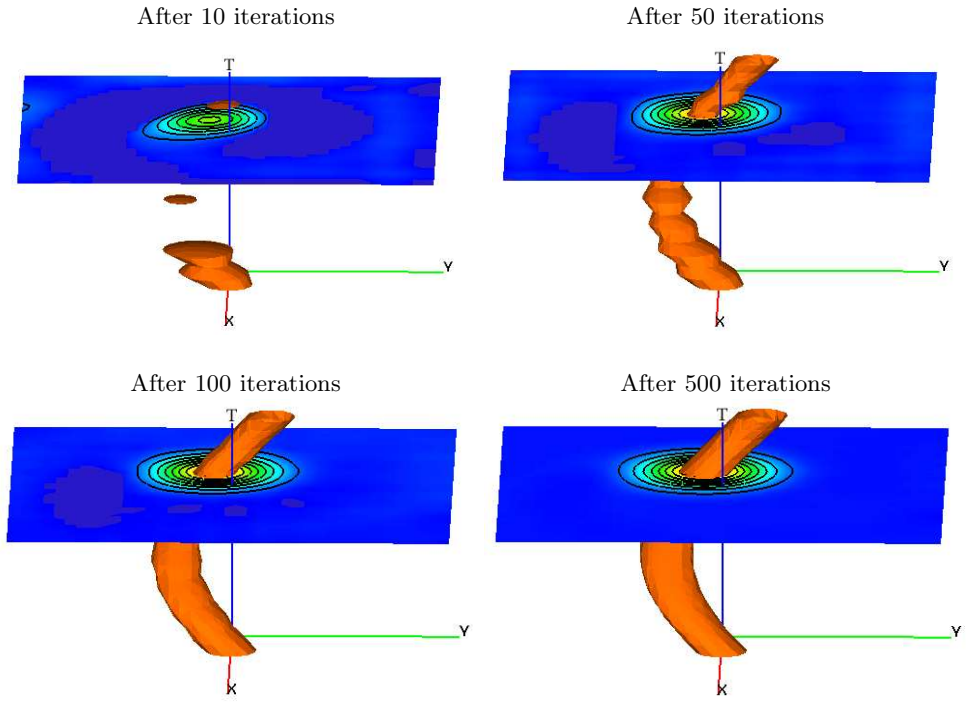

FIG. 3: An additive Schwarz preconditioned example in $2+1$ dimensions using five subdomains in time on a $40 \times 40 \times 20$ structured mesh, referenced in Table IV. The plots show the solution after 10,50,100, and 500 GMRES iterations. The isosurface indicates a surface with value of 0.8, tracking the motion of the pulse in time. A slice of the solution at time 3 is also shown with contour lines on the slice. The vertical axis is the time direction. Like Figure 2 in the $1+1$ dimension case, the solution is constructed at all timesteps at once rather than sequentially solving a single timestep at a time as in time marching methods

.

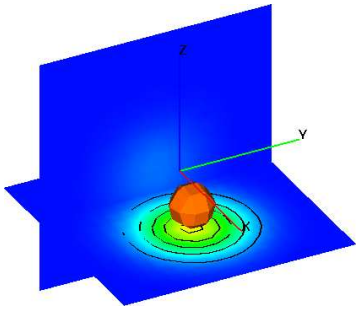

FIG. 4: Initial data for $3+1$ simulation in Figure 5.

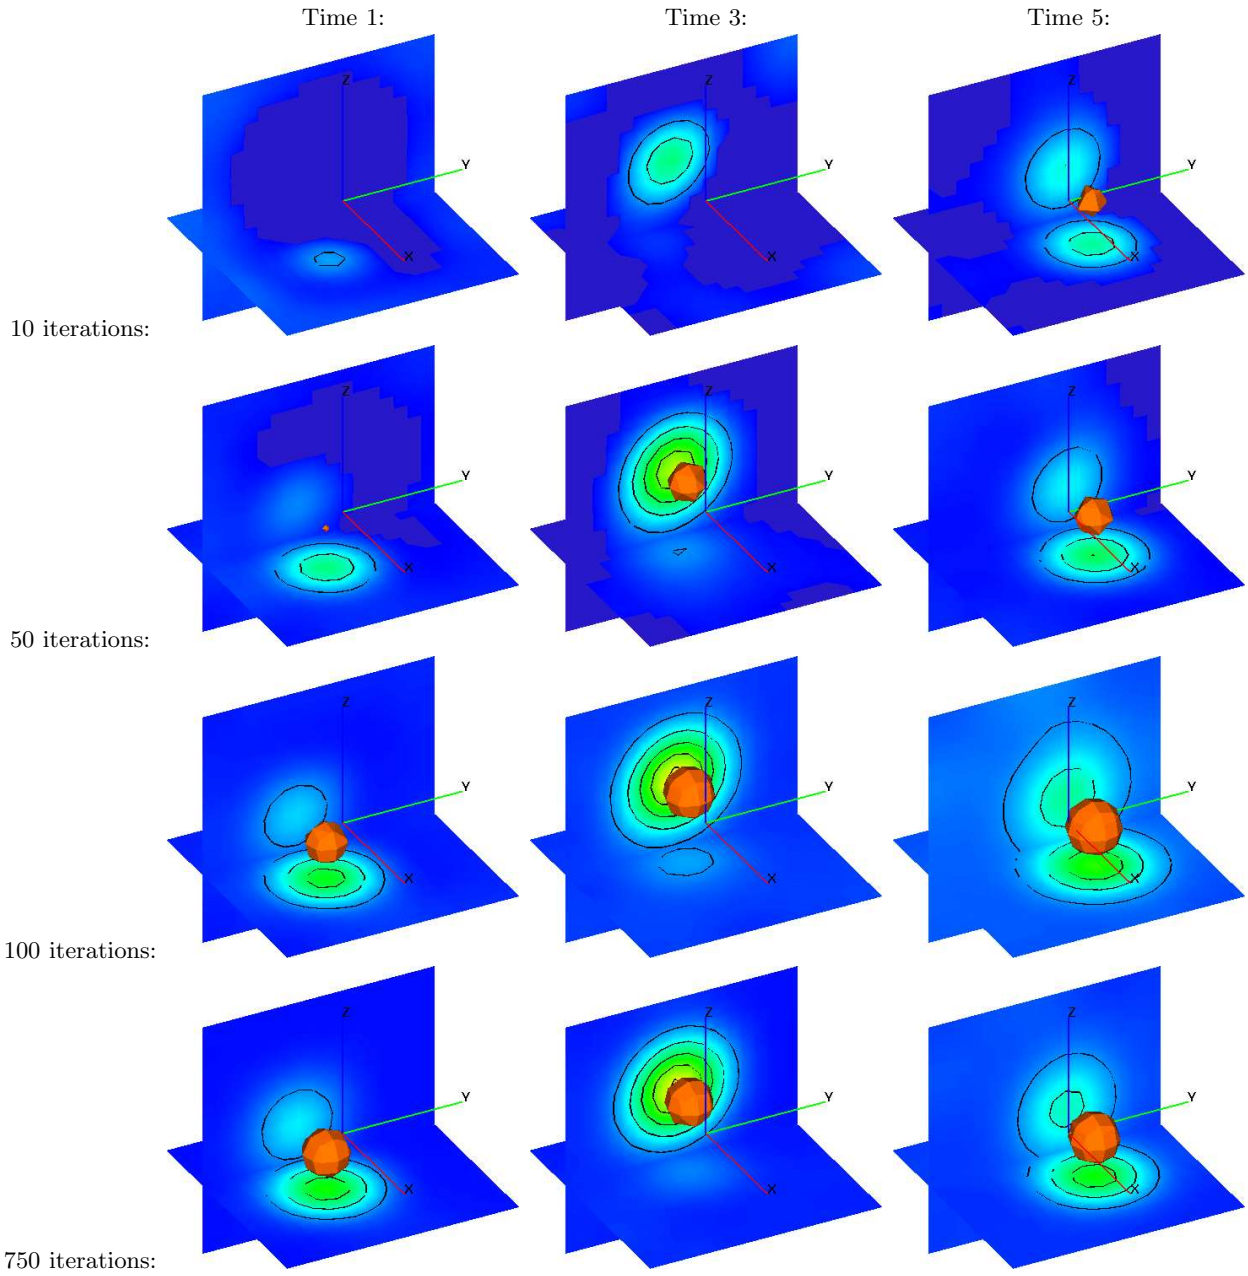

FIG. 5: The additive Schwarz preconditioned $3+1$ example using nine subdomains in time on a 18^4 structured mesh referred to in Table V. The initial data for this simulation is shown in Figure 4. The plots here show the solution, by row, after 10,50,100, and 750 GMRES iterations. The columns indicate the time of the solution: the left column shows the solution at time 1, the middle column shows time 3, and the right column shows time 5. An isosurface with value 0.8 tracks the motion of the pulse. Two spatial planes with contours are also shown: the first on the $x = -1$ plane, and the second on the $z = -1$ plane. Like Figures 2 and 3, the solution is constructed at all times simultaneously. The mesh consists of tesseracts, the higher dimensional analogue of hexahedra. The 3-D datasets shown are time slices from the 4-D mesh.

meshes in space and time can greatly simplify issues surrounding time-varying computational domains and space-time mesh refinement, provided that both the domain and refinement are specified a priori. They have also shown promise when the time-varying domain is not known a priori, as in [30] and [31]. We restricted our attention to those simulations which could be performed on a single processor. Fully implicit examples using a continuous time Galerkin method were presented in $1 + 1$, $2 + 1$, and $3 + 1$ dimensions using linear quadrilateral, hexahedral, and tesseractic

Solver Type	Preconditioner	# of subdomains	iterations	Final Residual	$\| (\tilde{u} - U_e) \|_{L_\infty}$
GMRES	ASM	6	300	10^{-4}	8.13×10^{-2}
GMRES	ASM	9	300	10^{-3}	8.53×10^{-2}
GMRES	ASM	9	600	10^{-3}	8.17×10^{-2}
GMRES	ASM	9	750	10^{-4}	8.15×10^{-2}

TABLE V: Linear solve results for the $3+1$ dimension case using an 18^4 structured mesh. The column labeled "Final Residual" gives the absolute residual norm for the linear solve. Unlike the $1+1$ and $2+1$ cases, these $3+1$ examples were only possible on a single processor because of the additive Schwarz preconditioning; both LU decomposition and unpreconditioned GMRES were impractical because of memory limitations or time limitations. These $3+1$ simulations used a mesh composed of linear tesseracts: 16 node 4-D hyperelements. Figure 4 shows the initial data used for these simulations; Figure 5 shows the solution for the nine subdomain ASM case after 10, 50, 100, and 750 GMRES iterations at three times: 1,3, and 5.

elements.

We found that LU decomposition and unpreconditioned GMRES were both capable of solving the linear systems which appear in these space-time element simulations. However, both choices scaled too poorly with respect to problem size to be effective even for moderate size simulations in $3+1$. Standard preconditioners like Jacobi and Block-Jacobi did not improve GMRES performance for the space-time linear systems.

We found that additive Schwarz preconditioning significantly improved GMRES performance. Substantial performance improvements were observed by applying a time decomposition strategy in additive Schwarz preconditioning. The time decomposition strategy consisted of decomposing the global mesh into several smaller time subdomains for use in preconditioning. This preconditioning strategy is also time-parallel: all the time subdomains used in preconditioning can be solved simultaneously on separate processors.

Several improvements upon the additive Schwarz preconditioner remain to be explored. In the experiments presented here, only face cell overlap was examined. Also, no attempt was made to combine time decomposition with spatial domain decomposition even though such a combination would be natural. A study of the optimal interface condition [32] is another interesting question since the interface condition explored here was physically motivated. Attempts at a parallel implementation of the preconditioner will be forthcoming. The substantial performance benefits of the ASM preconditioner make further study into space-time elements for numerical relativity feasible.

IV. ACKNOWLEDGEMENTS

Early prototyping benefited from two finite element packages: libmesh [33] and Diffpack [34]. We also acknowledge helpful discussions with Luis Lehner and Jorge Pullin. This work was supported by the following grants: NSF-PHY-0244335, NSF-PHY-0244299, nsf-int0204937, and NASA-NAG5-13430.
